Lists

['Demo']
Working with Lists

```python
>>> digits = [1, 8, 2, 8]

The number of elements

```python
>>> len(digits)
4

```python
An element selected by its index

```python
>>> digits[3]
8

```python
Concatenation and repetition

```python
>>> [2, 7] + digits * 2
[2, 7, 1, 8, 2, 8, 1, 8, 2, 8]

```python
Nested lists

```python
>>> pairs = [[10, 20], [30, 40]]

>>> pairs[1]
[30, 40]

>>> pairs[1][0]
30

```python
```
Containers
Containers

Built-in operators for testing whether an element appears in a compound value

```python
>>> digits = [1, 8, 2, 8]
>>> 1 in digits
True
>>> 8 in digits
True
>>> 5 not in digits
True
>>> not(5 in digits)
True
```
For Statements

(Demo)
def count(s, value):
    total = 0
    for element in s:
        if element == value:
            total = total + 1
    return total

Name bound in the first frame of the current environment (not a new frame)

if element == value:
    total = total + 1
return total
For Statement Execution Procedure

for <name> in <expression>:
    <suite>

1. Evaluate the header <expression>, which must yield an iterable value (a sequence)

2. For each element in that sequence, in order:
   A. Bind <name> to that element in the current frame
   B. Execute the <suite>
Sequence Unpacking in For Statements

A sequence of fixed-length sequences

```python
>>> pairs = [[1, 2], [2, 2], [3, 2], [4, 4]]

```  
```python
>>> same_count = 0

```  
```python
>>> for x, y in pairs:
...     if x == y:
...         same_count = same_count + 1

```  

```python
>>> same_count
2

```
Ranges
The Range Type

A range is a sequence of consecutive integers.*

\[ \ldots, -5, -4, -3, -2, -1, 0, 1, 2, 3, 4, 5, \ldots \]

\[ \text{range}(-2, 2) \]

**Length:** ending value - starting value

**Element selection:** starting value + index

```python
>>> list(range(-2, 2))
[-2, -1, 0, 1]
```

```python
>>> list(range(4))
[0, 1, 2, 3]
```

* Ranges can actually represent more general integer sequences.
List Comprehensions

```python
>>> letters = ['a', 'b', 'c', 'd', 'e', 'f', 'm', 'n', 'o', 'p']

>>> [letters[i] for i in [3, 4, 6, 8]]
['d', 'e', 'm', 'o']
```
List Comprehensions

[<map exp> for <name> in <iter exp> if <filter exp>]

Short version: [<map exp> for <name> in <iter exp>]

A combined expression that evaluates to a list using this evaluation procedure:

1. Add a new frame with the current frame as its parent
2. Create an empty result list that is the value of the expression
3. For each element in the iterable value of <iter exp>:
   A. Bind <name> to that element in the new frame from step 1
   B. If <filter exp> evaluates to a true value, then add the value of <map exp> to the result list
Strings
Strings are an Abstraction

Representing data:

'200'      '1.2e-5'      'False'      '[1, 2]'  

Representing language:

"""""""And, as imagination bodies forth
The forms of things unknown, the poet's pen
Turns them to shapes, and gives to airy nothing
A local habitation and a name.
"""""

Representing programs:

'curry = lambda f: lambda x: lambda y: f(x, y)'

(Demo)
String Literals Have Three Forms

```python
>>> 'I am string!'
'I am string!'

>>> "I've got an apostrophe"
"I've got an apostrophe"

>>> '您好'
'您好'

>>> """"The Zen of Python
claims, Readability counts.
Read more: import this."""
'The Zen of Python
claims, Readability counts.
Read more: import this.'
```

- Single-quoted and double-quoted strings are equivalent
- A backslash "escapes" the following character
- "Line feed" character represents a new line
Dictionaries

{"Dem": 0}
Limitations on Dictionaries

Dictionaries are *unordered* collections of key–value pairs

Dictionary keys do have two restrictions:

- A key of a dictionary **cannot be** a list or a dictionary (or any *mutable type*)

- Two **keys cannot be equal**; There can be at most one value for a given key

This first restriction is tied to Python's underlying implementation of dictionaries

The second restriction is part of the dictionary abstraction

If you want to associate multiple values with a key, store them all in a sequence value
