Box-and-Pointer Notation

The Closure Property of Data Types

- A method for combining data values satisfies the *closure property* if:

The result of combination can itself be combined using the same method

- Closure is powerful because it permits us to create hierarchical structures
- Hierarchical structures are made up of parts, which themselves are made up of parts, and so on

Lists can contain lists as elements (in addition to anything else)

Box-and-Pointer Notation in Environment Diagrams

Lists are represented as a row of index-labeled adjacent boxes, one per element
Each box either contains a primitive value or points to a compound value

```
pair = [1, 2]
```

Slicing

(Demo)

Slicing Creates New Values

```
1 digits = [1, 8, 2, 8]
2 start = digits[:1]
3 middle = digits[1:3]
4 end = digits[2:]
→ 5 full = digits[:]
```

Processing Container Values

Sequence Aggregation

Several built-in functions take iterable arguments and aggregate them into a value

- `sum(iterable[, start])` -> value

Return the sum of an iterable of numbers (NOT strings) plus the value of parameter 'start' (which defaults to 0). When the iterable is empty, return start.

- `max(iterable[, key=func])` -> value
`max(a, b, c, ..., key=func)` -> value

With a single iterable argument, return its largest item.
With two or more arguments, return the largest argument.

- `all(iterable)` -> bool

Return True if `bool(x)` is True for all values `x` in the iterable.
If the iterable is empty, return True.

Trees

Tree Abstraction

Recursive description (wooden trees):

A **tree** has a **root** and a list of **branches**

Each branch is a **tree**

A tree with zero branches is called a **leaf**

Relative description (family trees):

Each location in a tree is called a **node**

Each **node** has a **label value**

One node can be the **parent/child** of another

People often refer to values by their locations: "each parent is the sum of its children"

Implementing the Tree Abstraction

```
def tree(label, branches=[]):  
    return [label] + branches
```

```
def label(tree):  
    return tree[0]
```

```
def branches(tree):  
    return tree[1:]
```

- A tree has a label value and a list of branches

```
>>> tree(3, [tree(1),  
...         tree(2, [tree(1),  
...                 tree(1)])])  
[3, [1], [2, [1], [1]]]
```

Implementing the Tree Abstraction

```
def tree(label, branches=[]):  
    for branch in branches:  
        assert is_tree(branch)  
    return [label] + list(branches)  
  
def label(tree):  
    return tree[0]  
  
def branches(tree):  
    return tree[1:]  
  
def is_tree(tree):  
    if type(tree) != list or len(tree) < 1:  
        return False  
    for branch in branches(tree):  
        if not is_tree(branch):  
            return False  
    return True
```

Verifies the tree definition

Creates a list from a sequence of branches

Verifies that tree is bound to a list

- A tree has a label value and a list of branches

```
>>> tree(3, [tree(1),  
...         tree(2, [tree(1),  
...                 tree(1)])])  
[3, [1], [2, [1], [1]]]
```

```
def is_leaf(tree):  
    return not branches(tree)      (Demo)
```

Tree Processing

(Demo)

Tree Processing Uses Recursion

Processing a leaf is often the base case of a tree processing function

The recursive case typically makes a recursive call on each branch, then aggregates

```
def count_leaves(t):  
    """Count the leaves of a tree."""  
    if is_leaf(t):  
        return 1  
    else:  
        branch_counts = [count_leaves(b) for b in branches(t)]  
        return sum(branch_counts)
```

(Demo)

Discussion Question

Implement `leaves`, which returns a list of the leaf labels of a tree

Hint: If you `sum` a list of lists, you get a list containing the elements of those lists

```
>>> sum([ [1], [2, 3], [4] ], [])    def leaves(tree):
[1, 2, 3, 4]                          """Return a list containing the leaves of tree.
>>> sum([ [1] ], [])
[1]
>>> sum([ [[1]], [2] ], [])
[[1], 2]

>>> leaves(fib_tree(5))
[1, 0, 1, 0, 1, 1, 0, 1]
"""
if is_leaf(tree):
    return [label(tree)]
else:
    return sum(List of leaves for each branch, [])
```

`branches(tree)`

`leaves(tree)`

`[branches(b) for b in branches(tree)]`

`[leaves(b) for b in branches(tree)]`

`[b for b in branches(tree)]`

`[s for s in leaves(tree)]`

`[branches(s) for s in leaves(tree)]`

`[leaves(s) for s in leaves(tree)]`

Creating Trees

A function that creates a tree from another tree is typically also recursive

```
def increment_leaves(t):  
    """Return a tree like t but with leaf values incremented."""  
    if is_leaf(t):  
        return tree(label(t) + 1)  
    else:  
        bs = [increment_leaves(b) for b in branches(t)]  
        return tree(label(t), bs)  
  
def increment(t):  
    """Return a tree like t but with all node values incremented."""  
    return tree(label(t) + 1, [increment(b) for b in branches(t)])
```

Example: Printing Trees

(Demo)
