Object-Oriented Programming

A method for organizing programs
- Data abstraction
- Bundling together information and related behavior

A metaphor for computation using distributed state
- Each object has its own local state
- Each object also knows how to manage its own local state, based on method calls
- Method calls are messages passed between objects
- Several objects may all be instances of a common type
- Different types may relate to each other

Specialized syntax & vocabulary to support this metaphor

Classes

A class describes the general behavior of its instances.

Idea: All bank accounts have a balance and an account holder; the Account class should add those attributes to each newly created instance.

>>> a = Account('John')
>>> a.holder
'John'
>>> a.balance
0

Idea: All bank accounts should have withdraw and deposit behaviors that all work in the same way.

>>> a.deposit(15)
15
>>> a.withdraw(10)
5

Better idea: All bank accounts share a withdraw method and a deposit method.

Object Construction

Idea: All bank accounts have a balance and an account holder; the Account class should add those attributes to each of its instances.

>>> a = Account('Jim')

When a class is called:

1. A new instance of that class is created:

   An account instance

   balance: 0  holder: 'Jim'

2. The __init__ method of the class is called with the new object as its first argument (named self), along with any additional arguments provided in the call expression.

   class Account:
   def __init__(self, account_holder):
       self.balance = 0
       self.holder = account_holder

>>>

The Class Statement

A class statement creates a new class and binds that class to <name> in the first frame of the current environment.

Assignment & def statements in <suite> create attributes of the class (not names in frames).

>>> class Clown:
...
    nose = 'big and red'
    def dance():
        return 'No thanks'
...
>>> Clown.nose
'big and red'
>>> Clown.dance()
'No thanks'

class <name>:
<suite>  The suite is executed when the class statement is executed.

A class statement creates a new class and binds that class to <name> in the first frame of the current environment.

Assignment & def statements in <suite> create attributes of the class (not names in frames).
Object Identity

Every object that is an instance of a user-defined class has a unique identity:

```python
>>> a = Account('John')
>>> b = Account('Jack')
>>> a.balance 0
>>> b.holder 'Jack'
Identity operators "is" and "is not" test if two expressions evaluate to the same object:

```python
>>> a is a True
>>> a is not b True
``` 
Binding an object to a new name using assignment does not create a new object:

```python
>>> c = a
>>> c is a True
``` 

Methods

Methods are functions defined in the suite of a class statement

```python
class Account:
    def __init__(self, account_holder):
        self.holder = account_holder  # self should always be bound to an instance of the Account class
    def deposit(self, amount):
        self.balance = self.balance + amount  
        return self.balance
    def withdraw(self, amount):
        if amount > self.balance:
            return 'Insufficient funds'
        self.balance = self.balance - amount
        return self.balance
```

These def statements create function objects as always, but their names are bound as attributes of the class.

Invoking Methods

All invoked methods have access to the object via the self parameter, and so they can all access and manipulate the object's state

```python
class Account:
    def deposit(self, amount):
        self.balance = self.balance + amount
        return self.balance
```

Dot notation automatically supplies the first argument to a method

```python
>>> tom_account = Account('Tom')
>>> tom_account.deposit(100)
```
Dot Expressions

Objects receive messages via dot notation
Dot notation accesses attributes of the instance or its class

<expression> . <name>

The <expression> can be any valid Python expression
The <name> must be a simple name
Evaluates to the value of the attribute looked up by <name> in the object
that is the value of the <expression>

tom_account.deposit(10)

Dot expression
Call expression

Attributes

Accessing Attributes

Using getattr, we can look up an attribute using a string

>>> getattr(tom_account, 'balance')
10
>>> hasattr(tom_account, 'deposit')
True

ggetattr and dot expressions look up a name in the same way

Looking up an attribute name in an object may return:
• One of its instance attributes, or
• One of the attributes of its class

Methods and Functions

Python distinguishes between:
• Functions, which we have been creating since the beginning of the course, and
• Bound methods, which couple together a function and the object on which that
  method will be invoked

Object + Function = Bound Method

>>> type(Account.deposit)
<class 'function'>
>>> type(tom_account.deposit)
<class 'method'>

>>> Account.deposit(tom_account, 1001)
1011
>>> tom_account.deposit(1007)
2018

Function: all arguments within parentheses
Method: One object before the dot and
other arguments within parentheses
Looking Up Attributes by Name

To evaluate a dot expression:

1. Evaluate the `<expression>` to the left of the dot, which yields the object of the dot expression
2. `<name>` is matched against the instance attributes of that object; if an attribute with that name exists, its value is returned
3. If not, `<name>` is looked up in the class, which yields a class attribute value
4. That value is returned unless it is a function, in which case a bound method is returned instead

Class Attributes

Class attributes are "shared" across all instances of a class because they are attributes of the class, not the instance

```python
class Account:
    interest = 0.02  # A class attribute
    def __init__(self, account_holder):
        self.balance = 0
        self.holder = account_holder

    # Additional methods would be defined here
```

```python
>>> tom_account = Account('Tom')
>>> jim_account = Account('Jim')
>>> tom_account.interest
0.02
>>> jim_account.interest
0.02
```

The `interest` attribute is not part of the instance; it's part of the class!
