Call Expressions

Call expressions, such as `square(2)`, apply functions to arguments. When executing call expressions, we create a new frame in our diagram to keep track of local variables:

1. Evaluate the operator, which should evaluate to a function.
2. Evaluate the operands from left to right.
3. Draw a new frame, labelling it with the following:
   - A unique index (f1, f2, f3, ...).
   - The intrinsic name of the function, which is the name of the function object itself. For example, if the function object is `func square(x) [parent=Global]`, the intrinsic name is `square`.
   - The parent frame ([parent=Global]).
4. Bind the formal parameters to the argument values obtained in step 2 (e.g. bind x to 3).
5. Evaluate the body of the function in this new frame until a return value is obtained. Write down the return value in the frame.

If a function does not have a return value, it implicitly returns `None`. In that case, the “Return value” box should contain `None`.

**Note:** Since we do not know how built-in functions like `min(...)` or imported functions like `add(...)` are implemented, we do not draw a new frame when we call them, since we would not be able to fill it out accurately.

**Q1: Call Diagram**

Let’s put it all together! Draw an environment diagram for the following code. You may not have to use all of the blanks provided to you.

See the web version of this resource for the environment diagram.

Video diagram
Q2: Nested Calls Diagrams

Draw the environment diagram that results from executing the code below. You may not need to use all of the frames and blanks provided to you.

See the web version of this resource for the environment diagram.

Lambda Expressions

A lambda expression evaluates to a function, called a lambda function. For example, `lambda y: x + y` is a lambda expression, and can be read as “a function that takes in one parameter y and returns x + y.”

A lambda expression by itself evaluates to a function but does not bind it to a name. Also note that the return expression of this function is not evaluated until the lambda is called. This is similar to how defining a new function using a `def` statement does not execute the function’s body until it is later called.

```python
>>> what = lambda x : x + 5
>>> what
<function <lambda> at 0xf3f490>
```

Unlike `def` statements, lambda expressions can be used as an operator or an operand to a call expression. This is because they are simply one-line expressions that evaluate to functions. In the example below, `(lambda y: y + 5)` is the operator and 4 is the operand.

```python
>>> (lambda y: y + 5)(4)
9
>>> (lambda f, x: f(x))(lambda y: y + 1, 10)
11
```

Q3: Lambda the Environment Diagram

Draw the environment diagram for the following code and predict what Python will output.

See the web version of this resource for the environment diagram.
Higher Order Functions

A higher order function (HOF) is a function that manipulates other functions by taking in functions as arguments, returning a function, or both. For example, the function compose below takes in two functions as arguments and returns a function that is the composition of the two arguments.

```python
def composer(func1, func2):
    """Return a function f, such that f(x) = func1(func2(x))."""
    def f(x):
        return func1(func2(x))
    return f
```

HOFs are powerful abstraction tools that allow us to express certain general patterns as named concepts in our programs.

HOFs in Environment Diagrams

An environment diagram keeps track of all the variables that have been defined and the values they are bound to. However, values are not necessarily only integers and strings. Environment diagrams can model more complex programs that utilize higher order functions.

See the web version of this resource for the environment diagram.

Lambdas are represented similarly to functions in environment diagrams, but since they lack intrinsic names, the lambda symbol (λ) is used instead.

The parent of any function (including lambdas) is always the frame in which the function is defined. It is useful to include the parent in environment diagrams in order to find variables that are not defined in the current frame. In the previous example, when we call add_two (which is really the lambda function), we need to know what x is in order to compute x + y. Since x is not in the frame f2, we look at the frame's parent, which is f1. There, we find x is bound to 2.

As illustrated above, higher order functions that return a function have their return value represented with a pointer to the function object.
Q4: Make Adder

Draw the environment diagram for the following code:

See the web version of this resource for the environment diagram.

There are 3 frames total (including the Global frame). In addition, consider the following questions:

1. In the Global frame, the name \texttt{add\_ten} points to a function object. What is the intrinsic name of that function object, and what frame is its parent?
2. What name is frame \texttt{f2} labeled with (\texttt{add\_ten} or \texttt{add\_ten})? Which frame is the parent of \texttt{f2}?
3. What value is the variable \texttt{result} bound to in the Global frame?

You can try out the environment diagram at tutor.cs61a.org. To see the environment diagram for this question, click here.

1. The intrinsic name of the function object that \texttt{add\_ten} points to is \texttt{(specifically, the lambda whose parameter is k)}. The parent frame of this lambda is \texttt{f1}.
2. \texttt{f2} is labeled with the name \texttt{.} The parent frame of \texttt{f2} is \texttt{f1}, since that is where \texttt{.} is defined.
3. The variable \texttt{result} is bound to 19.

Q5: Make Keeper

Write a function that takes in a number \texttt{n} and returns a function that can take in a single parameter \texttt{cond}. When we pass in some condition function \texttt{cond} into this returned function, it will print out numbers from 1 to \texttt{n} where calling \texttt{cond} on that number returns \texttt{True}.

```python
def make_keeper(n):
    """Returns a function which takes one parameter cond and prints
    out all integers 1..i..n where calling cond(i) returns True."""

    def do_keep(cond):
        i = 1
        while i <= n:
            if cond(i):
                print(i)
            i += 1
        return do_keep

    >>> def is_even(x):
    ...     # Even numbers have remainder 0 when divided by 2.
    ...     return x % 2 == 0
    ... >>> make_keeper(5)(is_even)
    2
    4
    """
```

Note: This worksheet is a problem bank—most TAs will not cover all the problems in discussion section.
Currying

One important application of HOFs is converting a function that takes multiple arguments into a chain of functions that each take a single argument. This is known as currying. For example, the function below converts the `pow` function into its curried form:

```python
>>> def curried_pow(x):
    def h(y):
        return pow(x, y)
    return h

>>> curried_pow(2)(3)
8
```

Q6: Curry2 Diagram

Draw the environment diagram that results from executing the code below.

See the web version of this resource for the environment diagram.
**Extra Practice**

Feel free to reference this section as extra practice when studying for the exam in terms of tackling more involved or challenging problems.

**Q7: HOF Diagram Practice**

Draw the environment diagram that results from executing the code below.

See the web version of this resource for the environment diagram.

**Q8: Match Maker**

Implement `match_k`, which takes in an integer `k` and returns a function that takes in a variable `x` and returns `True` if all the digits in `x` that are `k` apart are the same.

For example, `match_k(2)` returns a one argument function that takes in `x` and checks if digits that are 2 away in `x` are the same.

`match_k(2)(1010)` has the value of `x = 1010` and digits 1, 0, 1, 0 going from left to right. `1 == 1` and `0 == 0`, so the `match_k(2)(1010)` results in `True`.

`match_k(2)(2010)` has the value of `x = 2010` and digits 2, 0, 1, 0 going from left to right. `2 != 1` and `0 == 0`, so the `match_k(2)(2010)` results in `False`.

**Important:** You may not use strings or indexing for this problem. You do not have to use all the lines, one staff solution does not use the line directly above the while loop.

**Hint:** Floor dividing by powers of 10 gets rid of the rightmost digits.
def match_k(k):
    """Return a function that checks if digits k apart match
    """
    def check(x):
        i = 0
        while 10 ** (i + k) < x:
            if (x // 10**i) % 10 != (x // 10 ** (i + k)) % 10:
                return False
            i = i + 1
        return True
    return check

Here's an alternate solution:

Note: This worksheet is a problem bank—most TAs will not cover all the problems in discussion section.
# Alternate solution

def match_k_alt(k):
    """ Return a function that checks if digits k apart match """

    >>> match_k_alt(2)(1010)
    True
    >>> match_k_alt(2)(2010)
    False
    >>> match_k_alt(1)(1010)
    False
    >>> match_k_alt(1)(1)
    True
    >>> match_k_alt(1)(2111111111111111)
    False
    >>> match_k_alt(3)(123123)
    True
    >>> match_k_alt(2)(123123)
    False
    """

def check(x):
    """
    def check(x):
        while x // (10 ** k):
            if (x % 10) != (x // (10 ** k)) % 10:
                return False
            x //= 10
        return True
    return check
