INSTRUCTIONS

- You have 2 hours to complete the exam.
- The exam is closed book, closed notes, closed computer, closed calculator, except one hand-written 8.5" × 11" crib sheet of your own creation and the official CS 61A midterm 1 study guide.
- Mark your answers on the exam itself. We will not grade answers written on scratch paper.

1. (10 points) I Wonder What Python Would Display

For each of the expressions in the table below, write the output displayed by the interactive Python interpreter when the expression is evaluated. The output may have multiple lines. If an error occurs, write "Error", but include all output displayed before the error. To display a function value, write “Function”. The first two rows have been provided as examples.

The interactive interpreter displays the value of a successfully evaluated expression, unless it is None.

Assume that you have first started python3 and executed the statements on the left.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Interactive Output</th>

2. (8 points) Environmental Influences

Fill in the environment diagram that results from executing the code below until the entire program is finished, an error occurs, or all frames are filled. You may not need to use all of the spaces, frames, or function values.

A complete answer will:

- Add all missing names and parent annotations to all local frames.
- Add all missing values created or referenced during execution.
- Show the return value for each local frame.

```python
x = 1
def f(n):
    def g():
        return n + x
    x = n + 5
    if n % 3 == 0:
        return g
    else:
        return f(n + 1)
x = 10
z = f(2)
q = x + z()
```

Global frame

```
func f(n) [parent=Global]

func _____ [parent=_____]

func _____ [parent=_____]

func _____ [parent=_____]

func _____ [parent=_____]

func _____ [parent=_____]

Return value
```

```
f1: _______ [parent=_______]

func _____ [parent=_____]

func _____ [parent=_____]

func _____ [parent=_____]

func _____ [parent=_____]

func _____ [parent=_____]

Return value
```

```
f2: _______ [parent=_______]

func _____ [parent=_____]

func _____ [parent=_____]

func _____ [parent=_____]

func _____ [parent=_____]

func _____ [parent=_____]

Return value
```

```
f3: _______ [parent=_______]

func _____ [parent=_____]

func _____ [parent=_____]

func _____ [parent=_____]

func _____ [parent=_____]

func _____ [parent=_____]

Return value
```
3. (3 points) Triangulate

It's easy to see that in any triangle, each side must be shorter than the sum of the other two. Implement `triangle`, which takes three positive numbers, a, b, and c, and returns whether these three numbers could possibly be the lengths of the three sides of a triangle.

```python
def triangle(a, b, c):
    
    return longest ___________________________________________________________ sum_of_others
```

```python
longest = ______________________________________________________________________________

sum_of_others = ________________________________________________________________________

return longest ___________________________________________________________ sum_of_others
```
4. (9 points) Digital

(a) (3 pt) Implement `collapse`, which takes a non-negative integer, and returns the result of removing all digits from it that duplicate the digit immediately to their right.

```python
def collapse(n):
    """For non-negative N, the result of removing all digits that are equal to the digit on their right, so that no adjacent digits are the same."
    left, last = n // 10, n % 10
    if ______________________________:  # Fill in the condition
        return last
    elif _______________ == ____________________________________________________________:
        return collapse(__________________________________________________________________)
    else:
        return collapse(___________________________) * 10 + ______________________________

>>> collapse(1234)
1234
>>> collapse(12234441)
12341
>>> collapse(0)
0
>>> collapse(3)
3
>>> collapse(1120000013333)
12013
"""
```

left, last = n // 10, n % 10

if ______________________________:  # Fill in the condition
    return last

elif _______________ == ____________________________________________________________:
    return collapse(__________________________________________________________________)

else:
    return collapse(___________________________) * 10 + ______________________________
(b) (6 pt) Implement `find_pair`, which takes a two-argument function, \( p \), as input and returns another function. The returned function takes a non-negative integer \( n \); it returns `True` if and only if \( p \) returns a true value when called on at least one pair of adjacent digits in \( n \), and `False` otherwise.

```python
def find_pair(p):
    """Given a two-argument function P, return a function that takes a non-negative integer and returns True if and only if two adjacent digits in that integer satisfy P (that is, cause P to return a true value).
    >>> z = find_pair(lambda a, b: a == b)  # Adjacent equal digits
    >>> z(1313)
    False
    >>> z(1234)
    True
    >>> z = find_pair(lambda a, b: a > b)
    >>> z(1234)
    False
    >>> z(123412)
    True
    >>> find_pair(lambda a, b: a <= b)(9753)
    False
    >>> find_pair(lambda a, b: a == 1)(1)  # Only one digit; no pairs.
    False
    """

def find(n):
    while ________________________________:
        if ________________________________:
            return ________________________________
        else:
            ----------- = ________________________________
```

```
5. (10 points) Please Confirm

Definition. A confirming function for a sequence of digits, called a code, takes a single digit as its only argument. If the digit does not match the first (left-most) digit of the code to be confirmed, it returns False. If the digit does match, then the confirming function returns True if the code has only one digit, or another confirming function for the rest of the code if there are more digits to confirm.

(a) (5 pt) Implement confirmer so that when confirmer takes a positive integer code, it returns a confirming function for the digits of that code.

def confirmer(code):
    """Return a confirming function for CODE.
    >>> confirmer(204)(2)(0)(4) # The digits of 204 are 2, then 0, then 4.
    True
    >>> confirmer(204)(2)(0)(0) # The third digit of 204 is not 0.
    False
    >>> confirmer(204)(2)(1)   # The second digit of 204 is not 1.
    False
    >>> confirmer(204)(20)    # The first digit of 204 is not 20.
    False
    """
    def confirm1(d, t):
        def result(digit):
            if d == digit:
                return t
            else:
                return False
        return result
    def extend(prefix, rest):
        """Return a confirming function that returns REST when given the digits of PREFIX. For example, if c = extend(12, confirmer(34)), then c(1)(2) returns confirmer(34), so that c is a confirming function for 1234."""
        left, last = prefix // 10, prefix % 10
        if ______________________________________________________________________________:
            return ______________________________________________________________________
        else:
            return ______________________________________________________________________
    return ______________________________________________________________________________
(b) (5 pt) Given a confirming function, one can find the code it confirms, one digit at a time. Implement `decode`, which takes a confirming function \( f \) and returns the code that it confirms.

```python
def decode(f, y=0):
    """Return the code for a confirming function \( f \)."""

    >>> decode(confirmer(12001))
    12001
    >>> decode(confirmer(56789))
    56789
    """

    d = 0

    while d < 10:

        x, code = _________________________________ , _________________________________

        if x == True:

            return code

        elif x == False:

            _________________________________

        else:

            _________________________________
```
