INSTRUCTIONS

- You have 2 hours to complete the exam.
- The exam is closed book, closed notes, closed computer, closed calculator, except one hand-written 8.5" × 11" crib sheet of your own creation and the official CS 61A midterm 1 study guide.
- Mark your answers on the exam itself. We will not grade answers written on scratch paper.

All the work on this exam is my own. (please sign)
1. (10 points)  I Wonder What Python Would Display *(All are in Scope: WWPD, Higher-Order Functions, Lambda Expressions)*

For each of the expressions in the table below, write the output displayed by the interactive Python interpreter when the expression is evaluated. The output may have multiple lines. If an error occurs, write “Error”, but include all output displayed before the error. To display a function value, write “Function”. The first two rows have been provided as examples.

The interactive interpreter displays the value of a successfully evaluated expression, unless it is `None`.
Assume that you have first started `python3` and executed the statements on the left.

<table>

2. (8 points) Environmental Influences (All are in Scope: Environment Diagrams, Higher-Order Functions)

Fill in the environment diagram that results from executing the code below until the entire program is finished, an error occurs, or all frames are filled. You may not need to use all of the spaces, frames, or function values.

A complete answer will:

- Add all missing names and parent annotations to all local frames.
- Add all missing values created or referenced during execution.
- Show the return value for each local frame.

```python
x = 1
def f(n):
    def g():
        return n + x
    x = n + 5
    if n % 3 == 0:
        return g
    else:
        return f(n + 1)
x = 10
z = f(2)
q = x + z()
```

Global frame

```
f1: [parent=_______]
    Return value |___

f2: [parent=_______]
    Return value |___

f3: [parent=_______]
    Return value |___
```
3. (3 points) Triangulate (All are in Scope: Control)

It's easy to see that in any triangle, each side must be shorter than the sum of the other two. Implement triangle, which takes three positive numbers, a, b, and c, and returns whether these three numbers could possibly be the lengths of the three sides of a triangle.

```python
def triangle(a, b, c):
    """Return whether a, b, and c could be the legs of a triangle."

    >>> triangle(3, 4, 5)
    True
    >>> triangle(3, 4, 6)
    True
    >>> triangle(6, 3, 4)
    True
    >>> triangle(3, 6, 4)
    True
    >>> triangle(9, 2, 2)
    False
    >>> triangle(2, 4, 2)
    False
    ""
    longest = ______________________________________________________________________________
    sum_of_others = ________________________________________________________________________
    return longest ___________________________________________________________ sum_of_others
```

```text
longest = ________________________________________________________________

sum_of_others = ____________________________________________________________

return longest ___________________________________________________________ sum_of_others
```
4. (9 points) Digital

(a) (3 pt) (**All are in Scope: Recursion**) Implement `collapse`, which takes a non-negative integer, and returns the result of removing all digits from it that duplicate the digit immediately to their right.

```python
def collapse(n):
    """For non-negative N, the result of removing all digits that are equal to the digit on their right, so that no adjacent digits are the same."
    left, last = n // 10, n % 10
    if last == last:  # If the last digit is equal to the digit on its right
        return last
    elif left == last:  # If the left digit is equal to the last digit
        return collapse(left)
    else:
        return collapse(left) * 10 + last
```

```bash
>>> collapse(1234)
1234
>>> collapse(12234441)
12341
>>> collapse(0)
0
>>> collapse(3)
3
>>> collapse(1120000013333)
12013
""
```
(b) (6 pt) (*All are in Scope: Control, Higher-Order Functions*) Implement `find_pair`, which takes a two-argument function, `p`, as input and returns another function. The returned function takes a non-negative integer `n`; it returns `True` if and only if `p` returns a true value when called on at least one pair of adjacent digits in `n`, and `False` otherwise.

```python
def find_pair(p):
    """Given a two-argument function P, return a function that takes a non-negative integer and returns True if and only if two adjacent digits in that integer satisfy P (that is, cause P to return a true value).
    >>> z = find_pair(lambda a, b: a == b)  # Adjacent equal digits
    >>> z(1313)
    False
    >>> z(12334)
    True
    >>> z = find_pair(lambda a, b: a > b)
    >>> z(1234)
    False
    >>> z(123412)
    True
    >>> find_pair(lambda a, b: a <= b)(9753)
    False
    >>> find_pair(lambda a, b: a == 1)(1)  # Only one digit; no pairs.
    False
    """
    def find(n):
        while ________________________________________________________________:
            if ________________________________________________________________:
                return _________________________________________________________
        else:
            ----------------- = ____________________________________________

```

5. (10 points) Please Confirm (**All are in Scope: Recursion, Higher-Order Functions**)

**Definition.** A confirming function for a sequence of digits, called a code, takes a single digit as its only argument. If the digit does not match the first (left-most) digit of the code to be confirmed, it returns False. If the digit does match, then the confirming function returns True if the code has only one digit, or another confirming function for the rest of the code if there are more digits to confirm.

(a) (5 pt) Implement confirmer so that when confirmer takes a positive integer code, it returns a confirming function for the digits of that code.

```python
def confirmer(code):
    """Return a confirming function for CODE."
    def confirm1(d, t):
        def result(digit):
            if d == digit:
                return t
            else:
                return False
        return result
    def extend(prefix, rest):
        """Return a confirming function that returns REST when given the digits of PREFIX. For example, if c = extend(12, confirmer(34)), then c(1)(2) returns confirmer(34), so that c is a confirming function for 1234."""
        left, last = prefix // 10, prefix % 10
        if ______________________________________________________________________________:
            return ______________________________________________________________________
        else:
            return ______________________________________________________________________
    return ______________________________________________________________________________
```

```python
def confirmer(code):
    """Return a confirming function for CODE."
    def confirm1(d, t):
        def result(digit):
            if d == digit:
                return t
            else:
                return False
        return result
    def extend(prefix, rest):
        """Return a confirming function that returns REST when given the digits of PREFIX. For example, if c = extend(12, confirmer(34)), then c(1)(2) returns confirmer(34), so that c is a confirming function for 1234."""
        left, last = prefix // 10, prefix % 10
        if ______________________________________________________________________________:
            return ______________________________________________________________________
        else:
            return ______________________________________________________________________
    return ______________________________________________________________________________
```
(b) (5 pt) Given a confirming function, one can find the code it confirms, one digit at a time. Implement `decode`, which takes a confirming function `f` and returns the code that it confirms.

def decode(f, y=0):
    """Return the code for a confirming function f."

    >>> decode(confirmer(12001))
    12001
    >>> decode(confirmer(56789))
    56789
    """

d = 0

    while d < 10:

        x, code = _________________________________ , _________________________________

        if x == True:

            return code

        elif x == False:

            __________________________________________________________

        else:

            __________________________________________________________
